                                                                         (labeled construction, n > 0)
                   aexp_{(acon)} \{ fbind_1, \dots, fbind_n \}
                                                                         (labeled update, n \geq 1)
```

Constructor

Constructor is one of the key elements to understand WHNF and lazy evaluation.

Constructor

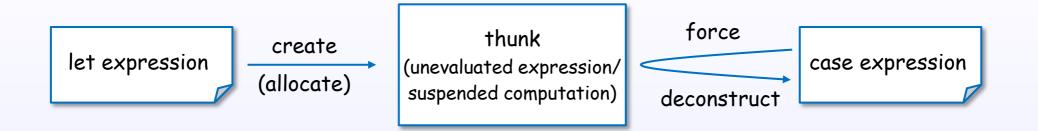

Thunk, let, case

Thunk

thunk (unevaluated expression/ suspended computation)

Thunk is an unevaluated expression in heap memory.

let/case expressions and thunk

A let expression may create a thunk.

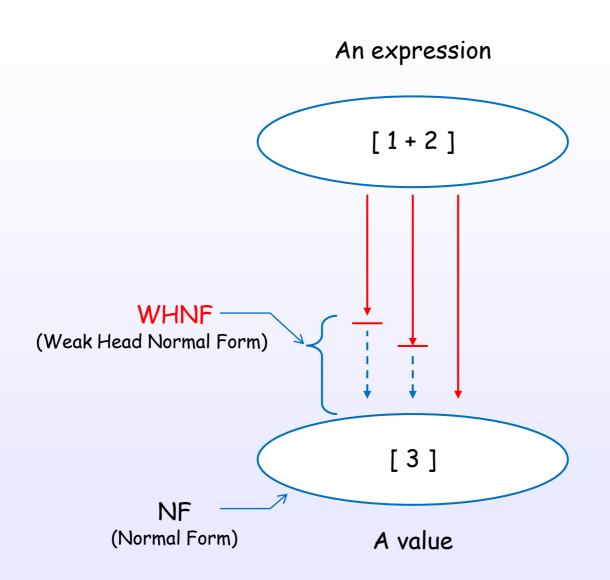

A case expression forces and deconstructs the thunk.

example

example, 要る? heap objectイメージは、後で?

There are some evaluation levels

[Terei]
[Bird, Chapter 2, 7]
[TAPL, Chapter 3]

WHNF

[4]

normal form: an expression without an redexes

head normal form:

an expression where the top level (head) is neither a redex NOR a lambda abstraction with a reducible body

weak head normal form: an expression where the top level (head) isn't a redex

[Terei]

WHNF

[4]

evaluation strategies:
call-by-value: arguments evaluated before function entered (copied)
call-by-name: arguments passed unevaluated
call-by-need: arguments passed unevaluated but an expression is only
evaluated once (sharing)

no-strict evaluation Vs. lazy evaluation:

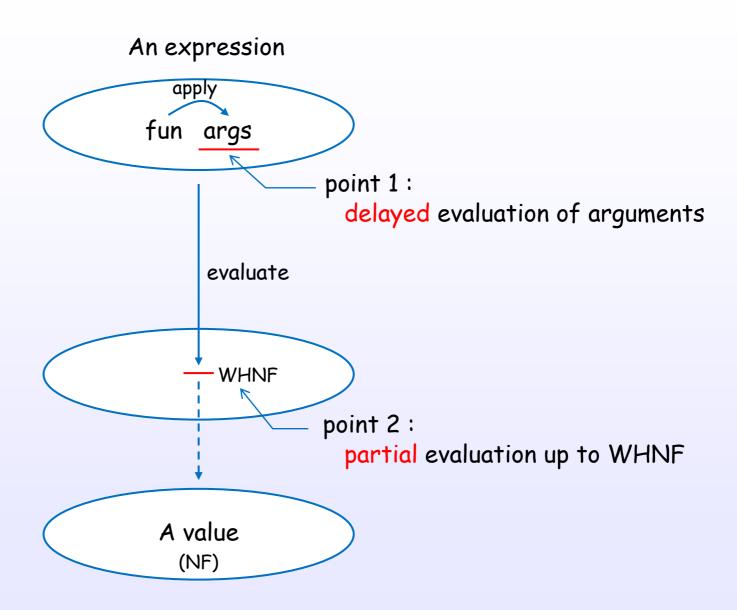

non-strict: Includes both call-by-name and call-by-need, general term for evaluation strategies that don't evaluate arguments before entering a function

lazy evaluation: Specific type of non-strict evaluation. Uses call-by-need (for sharing).

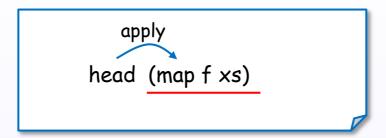

[Terei]

Evaluation in Haskell (GHC)

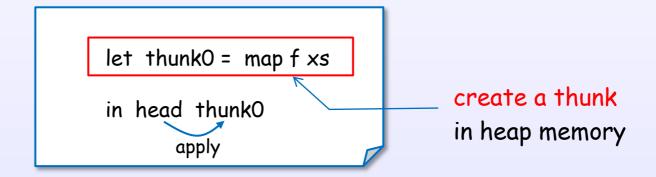

Key concept of Haskell's lazy evaluation

point 1: delayed evaluation of arguments

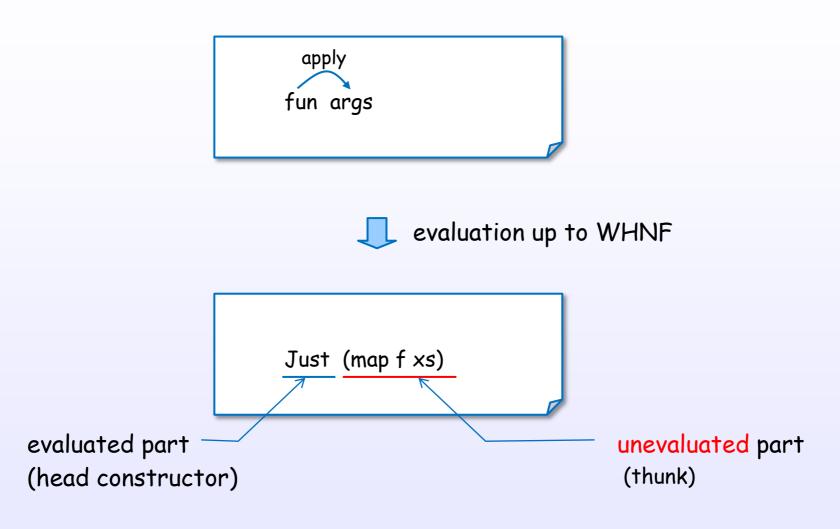

internal transformation by GHC

GHC implements lazy evaluation using the thunk. Evaluation of arguments is delayed with the thunk.

point 2: partial evaluation up to WHNF

GHC can partially evaluate a expression.

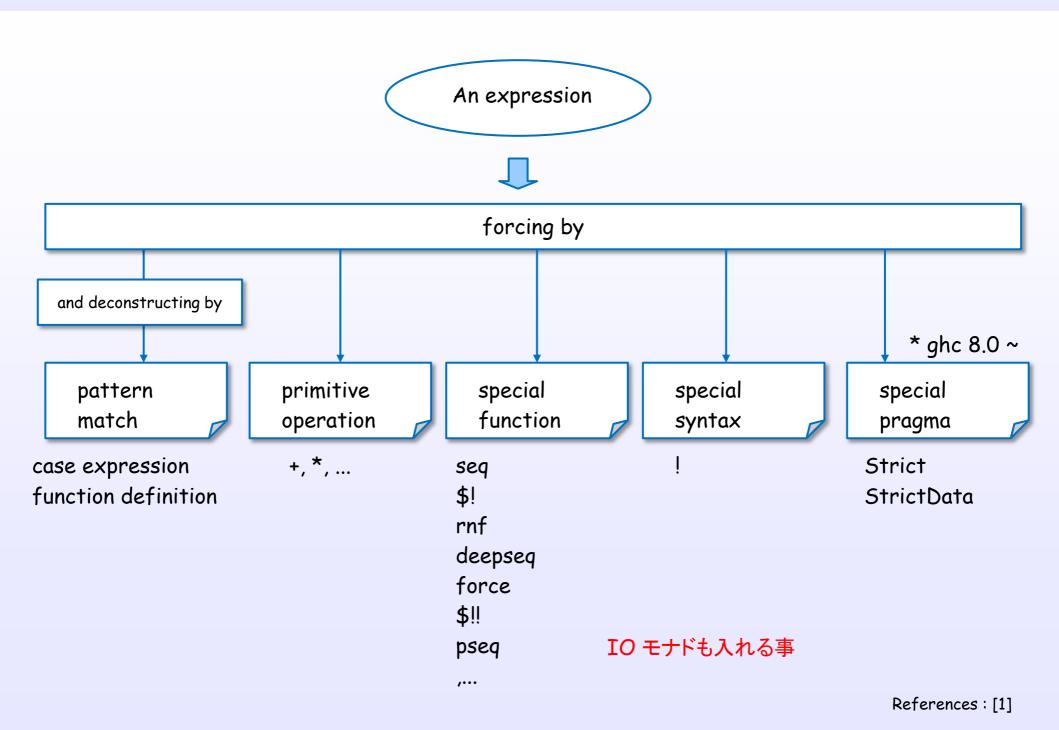

Constructor can hold an unevaluated expression (a thunk).

Pattern match
